

Vaccination Schedules

Smart Reminders Engine — kind = “vaccination”

PawGuard Platform | pawguard-backend (FastAPI + PostgreSQL + Redis + ARQ) | Prepared for Team Review

1. Purpose

Tracks each pet's upcoming vaccination due dates and reminds the owner automatically, so boosters (rabies, DHPP, etc.) don't get missed between vet visits.

2. Where It Lives

Vaccination reminders are not a separate table — they are pet_reminders rows with kind = “vaccination.” This keeps vaccination and medication reminders on one shared engine, schema, and delivery pipeline (see Automated Smart Reminders Engine doc for the full pipeline).

3. Key Fields Used for a Vaccination Reminder

Field	Example Value
kind	“vaccination”
title	“Rabies booster due”
details	Free text — dose, clinic notes, last administered date
due_at	Timestamp the vaccination is due
source_key	Unique key so the same due date is never double-scheduled

4. Typical Flow

1. A vaccination is logged as a medical record after a clinic visit (PetMedicalRecord, record_type = vaccination).
2. The owner (or clinic, on the owner's behalf) creates a follow-up reminder: POST /companion-pets/{pet_id}/reminders with kind = vaccination and the next-due date.
3. The daily 09:45 ARQ cron job picks up reminders due within the next 14 days and delivers them via in-app notification + email.
4. Owner sees it under GET /companion-pets/{pet_id}/reminders and can renew it after the next clinic visit.

5. Why This Matters for Reunification

An up-to-date vaccination history (visible via medical records) also strengthens an ownership claim during a lost-pet match review — staff can cross-check vet records against the claim.
