

Medication Push Notifications

Smart Reminders Engine — kind = “medication”

PawGuard Platform | pawguard-backend (FastAPI + PostgreSQL + Redis + ARQ) | Prepared for Team Review

1. Purpose

Reminds an owner to give a pet its medication on schedule — e.g. a daily heartworm tablet or a post-surgery course — using the same reminder engine as vaccinations, distinguished only by kind.

2. Key Fields Used for a Medication Reminder

Field	Example Value
kind	“medication”
title	“Heartworm tablet”
details	Dosage, frequency, prescribing vet
due_at	Next dose timestamp
source_key	Unique key per scheduled dose

3. Delivery = “Push” in Practice

“Push notification” here means the in-app notification service (and email) — the reminder is pushed to the owner rather than the owner having to check the app. Delivery is driven by the same daily 09:45 ARQ cron job described in the Smart Reminders Engine doc.

- `deliver_reminder_once()` guarantees a given dose reminder is never sent twice, thanks to the unique index on `pet_reminder_deliveries` (`reminder_id`, `user_id`, `scheduled_for`).
- A reminder can be deleted (`DELETE /companion-pets/{pet_id}/reminders/{reminder_id}`) once a medication course ends.

4. Recommended Enhancement for True Mobile Push

The current pipeline delivers via in-app notification + email. For native mobile push (APNs/FCM), a `device_token` table plus a push-provider integration in the notification service is the natural next step — the reminder scheduling logic itself would not need to change.

5. Example Timeline
